

# Final Project Q4

December 16, 2020

## 1 Q4

```
[3]: from part_a.ensemble import *  
     main()
```

Validation Accuracy is: 0.7012418854078465

Test Accuracy is: 0.6974315551792266

### Process:

For this ensemble process, we select IRT model developed in q2 as base model.

Steps: 1. Randomly select samples from train data (size is the same as the original data size). 2. Train the model with selected data. 3. Make predictions for validation and test data. 4. Repeat step 1-3 for 3 times and record the predictions for each round. 5. Average the predictions by formula

$$y_{bagged} = \mathbb{I}\left(\sum_{i=1}^m \frac{y_i}{m} > 0.5\right)$$

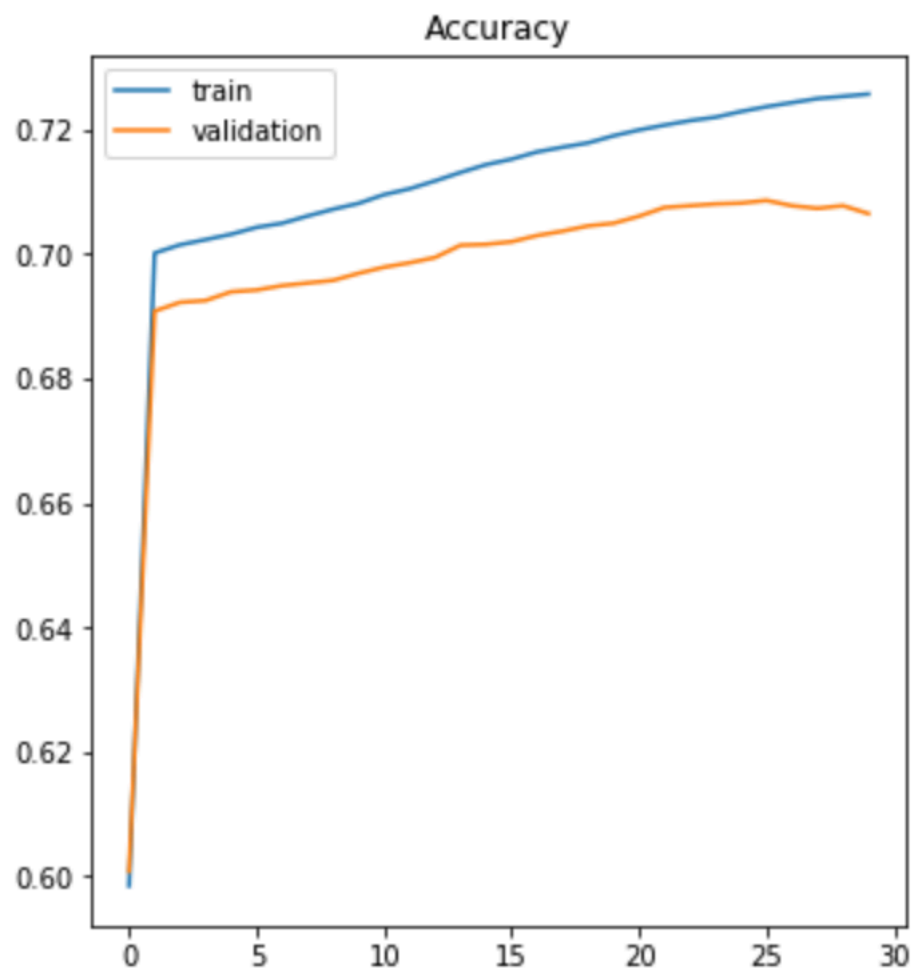

This is the same as taking a majority vote. 6. Calculate the accuracy using the final average predicted correctness.

### Do you obtain better performance using the ensemble? Why or why not?

**Ans:** No, we didn't obtain better performance using the ensemble. The ensembled accuracy (around 0.69) is always close to non-ensembled (around 0.69) accuracy. This might be because there is adequate data to train all models, the validation/test data matches the training distribution. Under this condition, generalizing data is relatively useless.

```
